**Abstract:** Pulmonary oxygen uptake on-kinetics provide insights into the processes underlying the increase in  $\text{O}_2$  flux from ambient air to muscle mitochondria following the onset of exercise. It is well known that aging from childhood to adulthood has a detrimental effect on the oxygen uptake on-kinetic response. Therefore, the aim of this study was to investigate the effects of aging on pulmonary oxygen uptake on-kinetics in nine youth elite-cyclists throughout a period of ~3 years. Participants visited the laboratory twice on three occasions within ~3 years. Anthropometric measures, a graded ramp-exercise test and two square-wave transitions from baseline to a constant work-rate within the moderate and heavy intensity exercise domain, respectively were conducted during these visits. The parameter estimates of the oxygen uptake on-kinetic response were resolved by least-squares non-linear regression. A repeated measures ANOVA was used for statistical analyses and the level of statistical significance was set at  $P < 0.05$ . During moderate and heavy intensity exercise, the time constant and the amplitude of the primary phase improved over time ( $P < 0.01$ ). However, the slow component evident during heavy intensity exercise was not significantly affected by time ( $P > 0.05$ ). These results suggest that regularly performed endurance training of elite youth-cyclists augments the potential for oxidative phosphorylation and reduces the impairments normally observed with aging.

**Keywords:**  $\text{VO}_2$  kinetics, endurance performance, youth athletes, oxidative phosphorylation, longitudinal monitoring

## 1. Introduction

Pulmonary oxygen uptake ( $\text{VO}_2$ ) on-kinetics provide insights into the processes underlying the increase in  $\text{O}_2$  flux from ambient air to muscle mitochondria following the onset of exercise. Therefore, the  $\text{VO}_2$  on-kinetic response is related to the  $\text{O}_2$  debt and ultimately exercise tolerance (Poole & Jones, 2012; Whipp & Wasserman, 1972).

A detrimental effect of aging (i.e. from childhood to adulthood) on the primary  $\text{VO}_2$  on-kinetic response and slow component has been shown consistently by a number of longitudinal and cross-sectional studies (Breese et al., 2010; Cooper et al., 1985;

Fawcner & Armstrong, 2004; Fawcner et al., 2002; Leclair et al., 2013; McNarry, 2019; Williams et al., 2001).

Therefore, the purpose of this study was to investigate the effects of aging on pulmonary  $\text{VO}_2$  on-kinetics during moderate and heavy intensity exercise in youth elite-cyclists throughout a period of ~3 years.

## 2. Materials and Methods

Nine trained youth elite-cyclists participated in this investigation. Prior to the study, the athletes and their legal guardians were informed of the experimental procedures and gave written informed consent to participate. The study was

58 conducted in accordance with the  
59 Declaration of Helsinki and approved by the  
60 institutional review board.

61 Participants visited the laboratory twice  
62 on three occasions within a period of ~3 years  
63 (Feb-2017, May-2018, Sep-2019).  
64 Anthropometric measures and a graded  
65 ramp-exercise test (GXT, 20 W.min<sup>-1</sup>) to  
66 determine peak oxygen uptake (VO<sub>2peak</sub>),  
67 maximal power (W<sub>max</sub>), ventilatory threshold  
68 (VT) and the intensity corresponding to 50%  
69 between VT and W<sub>max</sub> (Δ50%) were  
70 conducted during the first visit (see table 1  
71 for participant characteristics). On a  
72 subsequent visit, participants performed two  
73 square-wave transitions from a 3-min  
74 baseline at 40 W to a work-rate  
75 corresponding to 90% VT (moderate  
76 intensity) and Δ50% (heavy intensity),  
77 respectively. All tests were conducted on the  
78 participants own road bikes mounted on a  
79 Cyclus 2 ergometer (RBM Electronics,  
80 Leipzig, Germany). Gas exchange and  
81 pulmonary ventilation were measured  
82 continuously during the GXT and breath-by-  
83 breath during the square-wave transitions  
84 with a portable gas analyzer (MetaMax 3B,  
85 Cortex Biophysik, Leipzig, Germany).

86 To determine VO<sub>2</sub> kinetic parameters,  
87 breath-by-breath data were filtered, linearly  
88 interpolated at 1-second intervals and time  
89 aligned to the onset of exercise. To account  
90 for the cardio-dynamic phase the first 20 s of  
91 each square-wave transition were excluded  
92 from further analyses. The parameter  
93 estimates of the exponential primary phase  
94 (i.e. time constant (τ), amplitude) were  
95 resolved by least-squares regression  
96 (GraphPad Prism 8.4.3, GraphPad Software  
97 Inc., San Diego, CA, USA). The VO<sub>2</sub> slow  
98 component evident during heavy intensity  
99 exercise was calculated as the difference  
100 between end-exercise VO<sub>2</sub> and the  
101 amplitude.

102 Descriptive data are presented as mean  
103 ± standard deviation (SD). A repeated  
104 measures ANOVA was used for statistical  
105 analyses. Tukey's post-hoc test was used for  
106 multiple pairwise comparisons. The level of  
107 statistical significance was set at P < 0.05 two  
108 tailed for all tests.

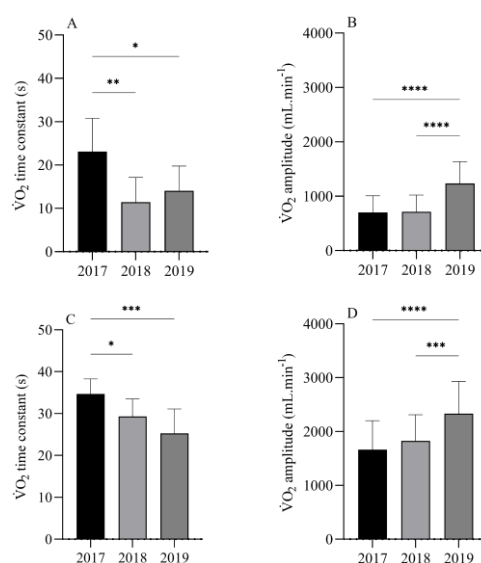

109 **Table 1.** Participants anthropometric  
110 characteristics and results of the graded ramp-  
111 exercise test as mean ± SD (n = 9).

	Feb 2017	May 2018	Sep 2019
Age (years)	14.5 ± 1.1	15.7 ± 1.0	16.7 ± 1.2
Stature (cm)	165 ± 13	171 ± 11	175 ± 11
Body mass (kg)	53.9 ± 12.7	59.1 ± 11.7	64.0 ± 11.1
WR <sup>1</sup> 90% VT <sup>2</sup> (W)	127 ± 27	135 ± 30	170 ± 34
WR <sup>1</sup> Δ50% (W)	218 ± 44	243 ± 48	279 ± 5
VO <sub>2peak</sub> <sup>3</sup> (mL.min <sup>-1</sup> .kg <sup>-1</sup> )	62.6 ± 4.2	61.1 ± 4.6	68.4 ± 7.6

112 <sup>1</sup> work-rate, <sup>2</sup> ventilatory threshold, <sup>3</sup> peak oxygen  
113 consumption, <sup>4</sup> maximal power.

### 114 3. Results

115 The parameter estimates of the primary  
116 phase VO<sub>2</sub> response for both square-wave  
117 transitions throughout the study are shown  
118 in figure 1. During moderate and heavy  
119 intensity exercise, τ significantly improved  
120 (i.e. was reduced) over time (90% VT: F<sub>2,16</sub> =  
121 7.18, P = 0.006; Δ50%: F<sub>2,16</sub> = 14.70, P < 0.001).  
122 As a result of the increased work rate during  
123 moderate and heavy intensity exercise, the  
124 amplitude significantly increased over time  
125 (90% VT: F<sub>2,16</sub> = 27.40, P < 0.001; Δ50%: F<sub>2,16</sub> =  
126 23.41, P < 0.001). For multiple pairwise  
127 comparisons see figure 1.

128

129 **Figure 1.** Primary phase  $\text{VO}_2$  time constant (Panel  
 130 A: 90% VT, Panel C:  $\Delta 50\%$ ) and amplitude (Panel  
 131 B: 90% VT, Panel D:  $\Delta 50\%$ ) throughout the study  
 132 duration. Tukey's post-hoc test: \*  $P < 0.05$ . \*\*  $P <$   
 133  $0.01$ . \*\*\*  $P < 0.001$ . \*\*\*\*  $P < 0.0001$ . VT = ventilatory  
 134 threshold.

135 The  $\text{VO}_2$  slow component was not  
 136 significantly affected by time (absolute:  $F_{2,16} =$   
 137  $3.34$ ,  $P = 0.061$ , relative:  $F_{2,16} = 0.76$ ,  $P = 0.456$ ,  
 138 see figure 2).

139 **Figure 2.** Heavy intensity exercise  $\text{VO}_2$  slow  
 140 component absolute (Panel A) and relative to the  
 141 amplitude (Panel B) throughout the study  
 142 duration.  
 143

#### 144 4. Discussion

145 The findings of this study are not in line  
 146 with previous longitudinal and cross-  
 147 sectional studies showing increases of the  
 148 moderate and/or heavy intensity exercise  
 149 primary phase  $\tau$  and the  $\text{VO}_2$  slow  
 150 component in untrained individuals with age  
 151 (i.e. from childhood to adulthood). These  
 152 previous findings suggest that aging (i.e.  
 153 from childhood to adulthood) is related with  
 154 a slowing and augmentation of the primary  
 155 phase  $\tau$  and the  $\text{VO}_2$  slow component,  
 156 respectively and therefore reduces the  
 157 potential for oxidative phosphorylation at  
 158 the onset of exercise (Armstrong & Barker,  
 159 2009; Breese et al., 2010; Cooper et al., 1985;  
 160 Fawkner & Armstrong, 2003; Fawkner &  
 161 Armstrong, 2004; Fawkner et al., 2002; Leclair  
 162 et al., 2013; McNarry, 2019; Williams et al.,  
 163 2001). In contrast, the results of the current  
 164 investigation suggest that regularly  
 165 performed endurance training of elite youth-  
 166 cyclists augments the potential for oxidative  
 167 phosphorylation and reduces the

168 impairments normally observed with aging.  
 169 However, these results must be interpreted  
 170 with caution due to the lack of a control  
 171 group.

#### 172 5. Practical Applications

173 Monitoring the pulmonary  $\text{VO}_2$  on-  
 174 kinetics may yield important information  
 175 about the potential for oxidative  
 176 phosphorylation at the onset of exercise  
 177 during the long-term athletic development of  
 178 youth elite-cyclists.
