14  
15 **1. Introduction**

16 Cycling can lead to traumatic injuries  
17 such as irritations or musculoskeletal pains  
18 which are caused by a bad interaction  
19 between the cyclist's buttocks and the saddle,  
20 causing an alteration of the perception of the  
21 sitting comfort (Breda et al. 2005; Larsen et al.  
22 2018). They are mainly due to tissue  
23 compressions or deformations that are  
24 associated with biomechanical seating  
25 factors, like the saddle surface pressure  
26 repartition or the shear forces.

27 Several studies investigated the  
28 effect of several saddles characteristics as the  
29 dimensions, the shapes, or their set up on the  
30 pressure repartition and perceived comfort  
31 (Hynd, Cooley, and Graham 2017; Larsen et  
32 al. 2018). However, an infinite number of  
33 saddles with different characteristics could  
34 exist, which makes it difficult to predict their  
35 impacts on the biomechanical and perceptual  
36 sitting factors.

37 To address this issue with car seating  
38 interfaces, several authors investigated the  
39 principle biomechanical seating variables  
40 that are associated with the seating perceived  
41 comfort during driving. The pressure  
42 repartition and the shear forces are the main  
43 parameters that impacted the seating  
44 comfort. Yet, no studies reported similar  
45 results during cycling (Beurier, Cardoso, and

46 Wang 2017; Hiemstra-van Mastrigt et al.  
47 2017).

48 Therefore, this preliminary study  
49 aimed to investigate the changes in saddle  
50 shear forces following an improvement of the  
51 sitting perceived comfort during cycling. We  
52 suggested that the lower dissipation of the  
53 force generated by the cyclist's buttock from  
54 the shear force would increase the force  
55 transmitted to the seat tube. Therefore, it is  
56 hypothesized that the improvement of the  
57 sitting perceived comfort will be associated  
58 with the increase of the tangential force  
59 transmitted to the seat tube.

60 **2. Materials and Methods**

61 Subjects- Four males (age:  $21.7 \pm 4.6$   
62 years, height:  $182.7 \pm 10.1$  cm; body mass:  $71.3$   
63  $\pm 14.2$  kg, body mass index:  $20.6 \pm 2.4$ ) and 1  
64 female (age: 25 years, height: 170 cm; body  
65 mass: 58 kg, body mass index: 20) trained  
66 competitive road cyclists volunteered to  
67 participate in the study. Subjects were  
68 accepted to participate in the study if they  
69 reported a perceived sitting comfort during  
70 their training on their road bike inferior or  
71 equal to 6 on the 0-10 VAS comfort scale (0  
72 No comfort – 10 Extremely strong comfort)  
73 (Kyung, Nussbaum, and Babski-Reeves  
74 2008).

75 Design- To compare biomechanical  
76 sitting factors before and after improvement

77 of the perceived sitting comfort, participants  
 78 performed with their personal bicycle two  
 79 times similar cycling exercises of 20 min on a  
 80 treadmill (RL2700E, Rodby, Sweden). It was  
 81 constituted of 4 blocks of 5 min with slopes of  
 82 1, 3, 6, and 9% respectively. The experimenter  
 83 controlled that both 5 min blocks performed  
 84 at the same slope during the two separated 20  
 85 min cycling exercises were performed with  
 86 the same gear ratio. The treadmill speed was  
 87 adjusted to clamp the participants close to a  
 88 RPE CR10 of 4 (Borg 1998). The sitting  
 89 comfort was assessed at the end of each 20  
 90 min session with the 0-10 VAS comfort scale  
 91 (0-very uncomfortable-10 very comfortable).  
 92 Moreover, saddle pressure and shear forces  
 93 measurements were performed with a saddle  
 94 pressure system (Gebiomized, Münster,  
 95 Germany), and a custom-made sensor (figure  
 96 1). Gebiomized saddle pressure system  
 97 allowed measuring the anterior-posterior  
 98 and medial-lateral mean displacement of the  
 99 force application point (in mm). The custom-  
 100 made sensor, by its conception, allowed  
 101 measuring the anterior-posterior and medial-  
 102 lateral tangential forces transmitted to the  
 103 seat tube. The amplitude of the time  
 104 synchronous average of the sensor signals  
 105 was calculated under Matlab (Matlab,  
 106 Mathworks, USA).

107 Between the first and the second  
 108 treadmill exercises, a fitting optimization  
 109 session was completed following the  
 110 Bikefitting institute recommendations  
 111 (Bikefitting, Maastricht, Netherland). This  
 112 aimed to improve the perceived sitting  
 113 comfort of the subjects. This session was  
 114 composed of 5 steps 1) perceived comfort  
 115 assessment during cycling and shoe cleats  
 116 settings; 2) anthropometrical  
 117 characterization; 3) dynamic fit; which aimed  
 118 to individually optimize the cyclist's  
 119 positions according to the bike fitting  
 120 recommendations; 4) pedaling analysis  
 121 which aimed to quantify and optimizing the  
 122 dynamic pedaling activity performed by the  
 123 cyclist's on both pedals, during the all  
 124 pedaling revolution; and 5) saddle model  
 125 selection and setup optimization; that  
 126 consisted in optimizing the sitting comfort of  
 127 subjects. According to the individual

128 problematics, different adjustments could be  
 129 performed as changes as saddle position and  
 130 model changes, handlebar position changes,  
 131 or shoe cleats setting.

132 Statistical Analysis- A non-parametric  
 133 Wilcoxon test was performed to investigate  
 134 the differences in the anterior-posterior and  
 135 medial-lateral tangential force transmitted to  
 136 the seat tube, application point force-  
 137 displacement, and perceived comfort  
 138 measurements assessed before and after the  
 139 fitting optimization session, during each 5-  
 140 min block of the treadmill tests. Cohen effect  
 141 size was calculated for each set of data  
 142 (Cohen, 1988). Cohen's  $d$  classification of  
 143 effect size magnitude was used, whereby  $d =$   
 144  $0.2-0.49 =$  small effect;  $d = 0.50-0.8 =$  moderate  
 145 effect and  $d > 0.8 =$  large effect. Data were  
 146 presented as median[interquartile range].

### 147 3. Results

148 After the fitting optimization session,  
 149 there was a statistical increase in the mean  
 150 tangential force amplitude in the anterior-  
 151 posterior direction (Me=36[37];  $+49 \pm 52\%$ ,  
 152  $p < 0.05$ ,  $d > 0.8$  at 1% slope; and Me=10[9];  $+36$   
 153  $\pm 66\%$ ,  $p < 0.05$ ,  $d > 0.8$  at 3% slope) and in the  
 154 medial-lateral force (Me=40[36];  $+33 \pm 22\%$ ,  
 155  $p < 0.05$ ,  $d > 0.8$  at 1% slope; and Me=10[8];  $+22$   
 156  $\pm 30\%$ ,  $p < 0.05$ ,  $d > 0.8$  at 3% slope), but not at  
 157 6 and 9% slopes (Figure 2). However, no  
 158 statistical difference was observed  
 159 concerning the point force-displacement in  
 160 these directions.

161 Finally, the perceived sitting comfort  
 162 increased after the fitting session ( $p < 0.001$ ,  
 163  $+180 \pm 109\%$ ; Figure 3).

#### 181 4. Discussion

182 The increase in tangential forces  
183 transmitted from the cyclists to the seat tube  
184 in the anterior-posterior and medial-lateral  
185 direction at a slope of 1% could be caused by  
186 the better stability of the pelvic on the saddle  
187 after the fitting session. Such hypotheses are  
188 supported by the absence of differences in  
189 the mean force application point  
190 displacement in the anterior-posterior and  
191 medial-lateral directions. This suggests a  
192 reduction in the dissipation of the tangential  
193 forces generated by the cyclists into shear  
194 forces between buttock tissues and the  
195 saddle. The absence of statistical increase in  
196 tangential forces transmitted to the seat tube  
197 for more important slopes (3, 6, and 9%)  
198 could be due to the gravity force promoting a  
199 pelvic retroversion. This would alter the

200 homogeneity of pressure repartition between  
201 the sit bones and the pubic, therefore altering  
202 the buttock stability on the saddle. Such  
203 evolution of these biomechanical sitting  
204 factors would participate in the improvement  
205 of the sitting perceived comfort in cycling.  
206 Optimizing such biomechanical parameters  
207 would allow the prevention of sitting-related  
208 traumatic injuries in cycling.
